⚡ Suspense Boundaries: React vs Next.js

Developer Overview — Master Luna's Village Dev Series

What is a Suspense Boundary?

A `<Suspense>` boundary is a React component that **catches children that are "not ready yet"** and shows a fallback UI (spinner, skeleton) until they finish loading.

```
<Suspense fallback={<LoadingSpinner />}>
  <SlowComponent />
</Suspense>
```

Think of it as a **try/catch — but for loading states**, not errors.

React Suspense (Core)

How it works

React Suspense works by catching a **thrown Promise** from a child component. When a component isn't ready, it "suspends" — React shows the fallback until the data resolves.

What triggers Suspense in React

Trigger	Supported?
`React.lazy()` (code splitting)	✅ Yes
`use()` hook with a Promise	✅ Yes
Suspense-enabled frameworks (Relay)	✅ Yes
`useEffect` data fetching	❌ No
Event handler fetching	❌ No

Basic Example

```
import { Suspense, lazy } from 'react';

const HeavyChart = lazy(() => import('./HeavyChart'));

function Dashboard() {
  return (
    <Suspense fallback={<div>Loading chart...</div>}>
      <HeavyChart />
    </Suspense>
  );
}
```

Nested Boundaries — Progressive Loading

```
function ArtistPage() {
  return (
    <Suspense fallback={<PageSpinner />}>          {/* outer */}
      <Biography />
      <Suspense fallback={<AlbumsSkeleton />}>    {/* inner */}
        <Albums />
      </Suspense>
    </Suspense>
  );
}
```

Loading sequence:

1. User sees `<PageSpinner />`
2. `<Biography />` loads → user sees it immediately
3. `<Albums />` still loading → user sees `<AlbumsSkeleton />`
4. `<Albums />` done → full page visible

Preventing Jarring Fallbacks with `startTransition`

```
import { startTransition } from 'react';

function NavLink({ to }) {
  return (
    <button onClick={() => {
      startTransition(() => setPage(to)); // keeps old content, no flash
    }}>
      Go
    </button>
  );
}
```

Using `use()` with Suspense (React 19+)

```
// Parent passes down a promise — does NOT await it
function Page() {
  const postsPromise = getPosts(); // not awaited!
  return (
    <Suspense fallback={<PostsSkeleton />}>
      <Posts promise={postsPromise} />
    </Suspense>
  );
}

// Child consumes the promise — this triggers Suspense
'use client';
import { use } from 'react';
```

```
function Posts({ promise }) {
  const posts = use(promise); // suspends here until resolved
  return <ul>{posts.map(p => <li key={p.id}>{p.title}</li>)}</ul>;
}
```

Next.js Suspense (App Router)

Next.js **builds on top of React Suspense** and adds its own conventions and SSR streaming capabilities.

Method 1: `loading.js` — The Convention (Automatic Suspense)

Create a `loading.js` or `loading.tsx` file **next to your `page.js`**. Next.js **automatically wraps your page in a `<Suspense>` boundary** for you.

```
app/
  dashboard/
    loading.tsx     ← auto Suspense fallback
    page.tsx        ← your page (async Server Component)
    layout.tsx
```

```
// app/dashboard/loading.tsx
export default function Loading() {
  return <DashboardSkeleton />;
}
```

```
// app/dashboard/page.tsx
export default async function DashboardPage() {
  const data = await fetchDashboardData(); // loading.tsx shows meanwhile
  return <Dashboard data={data} />;
}
```

What Next.js does under the hood:

```
// Next.js generates this automatically:
<Suspense fallback={<Loading />}>
  <Page />
</Suspense>
```

Method 2: Manual `<Suspense>` — Granular Streaming

```
// app/dashboard/page.tsx
import { Suspense } from 'react';

export default async function Page() {
  return (
    <main>
      <h1>Dashboard</h1>
```

```
      {/* These stream independently — parallel! */}
      <Suspense fallback={<CardsSkeleton />}>
        <RevenueChart />
      </Suspense>

      <Suspense fallback={<CardsSkeleton />}>
        <LatestInvoices />
      </Suspense>
    </main>
  );
}
```

```
// components/RevenueChart.tsx — async Server Component
async function RevenueChart() {
  const revenue = await fetchRevenue(); // owns its own data
  return <BarChart data={revenue} />;
}
```

Sequential vs Parallel Fetching

Sequential (one depends on the other)

```
export default async function Page({ params }) {
  const artist = await getArtist(params.username);

  return (
    <>
      <h1>{artist.name}</h1>
      <Suspense fallback={<PlaylistSkeleton />}>
        <Playlists artistID={artist.id} />
      </Suspense>
    </>
  );
}
```

Parallel (independent — faster!)

```
export default async function Page({ params }) {
  // Fire both at the same time
  const artistPromise = getArtist(params.username);
  const albumsPromise = getAlbums(params.username);

  const [artist, albums] = await Promise.all([artistPromise, albumsPromise]);

  return (
    <>
      <h1>{artist.name}</h1>
      <Albums list={albums} />
```

```
    </>
  );
}
```

React vs Next.js — Side by Side

Feature	React (Vanilla)	Next.js (App Router)
Manual `<Suspense>` wrapping	✅	✅
`loading.js` auto-wrapping	❌	✅
SSR streaming to browser	Requires setup	✅ Built-in
Async Server Components	❌ (client only)	✅
`use()` hook support	✅ React 19+	✅
`React.lazy()`	✅	✅ (client components)
Layout protection	❌	✅

Next.js Suspense Best Practices

✅ Do

- Move slow fetches into their own async Server Components so they stream independently
- Use `loading.js` for full route segment loading states
- Use manual `<Suspense>` for granular control within a page
- Prefer `Promise.all()` for independent parallel fetches
- Give each Suspense boundary a meaningful, component-specific skeleton

❌ Avoid

- Awaiting multiple independent fetches sequentially at the top of a page
- Wrapping layouts in `<Suspense>` (they should be stable shells)
- Skipping `loading.js` when you have slow top-level page fetches
- Using a single global spinner for the whole page when parts can load independently

---

The Mental Model

```
Without Suspense:              With Suspense (streaming):
_________________              __________________________

[                ]             [ Layout    ✅ immediate ]
[   waiting...   ]    →        [ Header    ✅ immediate ]
[                ]             [ ▒▒ Skeleton loading... ]
[   nothing      ]             [ Content   ✅ streamed  ]
[   visible      ]
```

Next.js + Suspense lets you **ship the shell fast** and **stream data in progressively** — making apps feel dramatically faster even on slow connections.
